CRYSTAL STRUCTURE VI

Field of the Invention

The present invention relates to the provision of high resolution crystal structures of the prokaryotic 30S ribosome subunit in complex with tRNA and a cognate mRNA, both in the presence and absence of the antibiotic paromomycin. The invention also provides for the use of these structures in drug discovery.

Background of the Invention

During protein synthesis, the ribosome catalyzes the sequential addition of amino acids to a growing polypeptide chain using messenger RNA (mRNA) as a template and aminoacylated transfer RNAs (aa-tRNAs) as substrates. Correct base pairing between the three bases of the codon on mRNA and those of the anticodon of the cognate aa-tRNA dictates the sequence of the polypeptide chain. Discrimination against non-cognate tRNA, which generally has two or three mismatches in the base pairing, can be accounted for by the difference in the free energy of base pairing to the codon compared to cognate tRNA. For near-cognate tRNA, which usually involves a single mismatch, the free energy difference in base pairing compared to cognate tRNA would predict an error rate that is 1-2 orders of magnitude higher than the actual error rate of protein synthesis (reviewed in (1)), and it has long been recognized that the ribosome must improve the accuracy of protein synthesis by discriminating against near-cognate tRNAs (2). This discrimination involves the 30S subunit, which binds mRNA and the anticodon stem-loop (ASL) of tRNA.

At the beginning of the elongation cycle, which involves the addition of a new amino acid to a growing polypeptide chain, the aa-tRNA is presented to the ribosome as a ternary complex with elongation factor Tu (EF-Tu) and guanosine triphosphate

(GTP). The selection of cognate tRNA is believed to occur in two stages, an initial recognition step and a proofreading step, that are separated by the irreversible hydrolysis of GTP by EF-Tu (3-6). In this scheme, the discrimination energy inherent in codon-anticodon base pairing is exploited twice to achieve the necessary accuracy. Recent experiments suggest that the binding of cognate rather than near-cognate tRNA results in higher rates of both GTP hydrolysis by EF-Tu, and accommodation, a process in which the acceptor arm of the aa-tRNA swings into the peptidyl transferase site after its release from EF-Tu (7, 8). In both steps, the higher rate is proposed to be the result of structural changes in the ribosome induced by cognate tRNA. In the context of proofreading mechanisms alone, it is unclear whether additional structural discrimination by the ribosome, over that inherent in the energetics of codon-anticodon base pairing, is actually required in decoding. In an alternative view, it was proposed that the ribosome contributes to the specificity of decoding by recognizing the geometry of codon-anticodon base pairing (9, 10), probably by direct recognition of the sugar phosphate backbone (11). This is consistent with evidence that the ribosome can discriminate between cognate and near-cognate tRNA with very high accuracy in a single step under near-equilibrium conditions (12), so that the recognition and proofreading steps may be needed not just for accuracy as proposed earlier, but for the combination of high speed and accuracy required in protein synthesis.

The heart of decoding involves recognition of Watson-Crick base-pairing between the codon on mRNA and the anticodon found in positions 34-36 of the ASL of tRNA. This base pairing results in a short double helix that we refer to as the codon-anticodon helix. Data from chemical protection (13), cross-linking (14) and genetic analysis (15) suggest that the decoding site is a region around the ribosomal A site that

includes helix 44, the 530 loop and helix 34 of 16S RNA, which are now known from the high resolution structure of the 30S subunit to be close to one another (16, 17).

Recent work on decoding has focused on an internal loop of helix 44 containing two universally conserved bases, A1492 and A1493. These bases are chemically protected at their N1 positions when tRNA is bound in the A site of the 30S subunit (13), and were shown to be essential for viability in *E. coli* and for A-site tRNA binding (18). This loop is also the binding site of the antibiotic paromomycin that reduces the fidelity of decoding (19-21). NMR structures of a fragment of RNA containing this internal loop showed that these bases were displaced into the minor groove of helix 44 in the presence of paromomycin (20, 22). A direct interaction of the N1 of these bases with the 2' OH of mRNA was inferred on the basis of biochemical experiments (18). Based on these data, it was suggested that the changes induced by the antibiotic mimic those induced by cognate tRNA, that the bases would interact via their minor groove side with the minor groove of the codon-anticodon helix, and that they would sense the shape of the codon-anticodon helix during decoding (18, 20, 22). However, in the absence of a structure in the context of the whole 30S subunit, it was also possible to use existing data to propose an alternative and quite different model of the decoding site that involved interaction of the codon-anticodon helix with the major rather than minor groove of helix 44 (23).

A 7.8 Å resolution structure of the 70S ribosome in complex with mRNA and tRNA (24) showed that at that resolution, the conformation of the internal loop in helix 44 was similar to that in the paromomycin-bound NMR structure of the isolated fragment (20). However, A1492 and A1493 in this internal loop appeared too far from the codon-anticodon helix to interact

with it directly (24), so their role and the general structural basis of decoding by the ribosome remained unclear.

More recently, the crystal structure of the 30S subunit complexed with paromomycin, streptomycin and spectinomycin (21) showed that A1492 and A1493 are in fact completely flipped out from their stacked position inside the internal loop rather than just displaced into the minor groove as previously proposed (20). The displaced bases point into the A site in a position that would indeed allow direct monitoring of the minor groove of the codon-anticodon helix. On the basis of this structure, we suggested that during decoding, these bases would flip out even in the absence of paromomycin, in a way that would allow discrimination of cognate from near-cognate tRNA (21). However, this conformation would place the N1 of the adenines pointing towards tRNA, and hence unable to make the interactions with mRNA previously reported (18).

Summary of the Invention

We have examined the interactions of the 30S subunit with mRNA and an anticodon stem-loop of cognate tRNA bound in the A site by x-ray crystallography. The x-ray crystal structure of this complex is provided by Table 1 below.

We have also formed a 30S complex which in addition to tRNA and mRNA includes the antibiotic, paromomycin. The x-ray crystal structure of this complex is provided by Table 2 below.

By way of comparison, we have also determined the x-ray crystal structure of paromomycin bound to the 30S ribosome. This is provided by Table 3 below.

In a first aspect, the present invention provides a crystal of the *Thermus thermophilus* 30S subunit bound to a tRNA molecule

and a cognate mRNA, having a tetragonal space group $P4_12_12$ with unit cell dimensions of a = 401.6 Å, b = 401.6 Å and c = 176.1 Å.

In a second aspect, the present invention provides a crystal of the *Thermus thermophilus* 30S subunit bound to a tRNA molecule, a cognate mRNA and paromomycin having a tetragonal space group $P4_12_12$ with unit cell dimensions of a = 400.8 Å, b = 400.8 Å and c = 175.9 Å.

In a third aspect, the present invention provides a crystal of the *Thermus thermophilus* 30S subunit bound to paromomycin having a tetragonal space group $P4_12_12$ with unit cell dimensions of a = 401.2 Å, b = 401.2 Å and c = 176.4 Å.

An advantageous feature of these structures are that they diffract at about a 3Å resolution. Another feature of the structures are that it was obtained in a method which did not involve soaking crystals in heavy atom (e.g. tungsten or tantalum) clusters or heat activation. Furthermore, it is specifically of the 885-888/910-912 base pairing confirmation of 16S RNA. These features, both singly and in combination all contribute to features of the invention which are advantageous.

In a related aspect, the invention also provides a crystal of 30S bound to a tRNA molecule and a cognate mRNA having the three dimensional atomic coordinates of Table N, where N is selected from 1, 2 or 3. Reference herein to Table N is hereafter a reference to any one of these tables.

We have also observed that 30S crystals do not contain the S1 subunit protein. In our studies, we have found that by selectively removing this protein prior to crystallization, we have been able to obtain the improved resolution described

herein. Although the atomic co-ordinates provided in Table N below allows those of skill in the art to bypass the need to undertake the crystallization of the 30S, this crystallization method nonetheless forms a further aspect of the invention.

Accordingly, there is provided a method for crystallizing a the 30S subunit to obtain a high resolution structure of a 30S subunit, which method comprises providing a 30S subunit, selectively removing the S1 subunit therefrom, crystallizing the 30S and soaking into the crystals either (i) tRNA and a cognate mRNA, and/or (ii) an antibiotic, particularly one which acts at the site of tRNA recognition or mRNA synthesis such as paromomycin. This aspect of the invention may be performed with any tRNA molecule and any mRNA with a cognate codon, not only the specific tRNA and mRNA of the accompanying example.

In a further aspect, the present invention provides a method for identifying a potential inhibitor of the 30S comprising the steps of:

employing a three-dimensional structure of 30S, or at least one sub-domain thereof, to characterize at least one site bound by tRNA or mRNA, the three-dimensional structure being defined by atomic coordinate data according to Table N; and

identifying the potential inhibitor by designing or selecting a compound for interaction with the site.

In a further aspect, the present invention provides computer readable media with either (a) atomic coordinate data according to Table N recorded thereon, said data defining the three-dimensional structure of 30S or at least one sub-domain thereof, or (b) structure factor data for 30S recorded thereon, the structure factor data being derivable from the atomic coordinate data of Table N.

Detailed Description of the Invention.

Definitions.

The term "sub-domain" includes the following:

(a) and element selected from the following:

at least one complete element of secondary structure, i.e. an alpha helix or a beta sheet, or RNA helix, as described in the detailed description below;

a group of two or more such elements which interact with each other;

at least one subunit protein;

a subgroup of subunit proteins, for example a group which includes two or more proteins which are found to interact with each other;

any of the above, when being protein or element thereof being used in conjunction with all or part of the 16S RNA structure associated with said elements or proteins;

(b) a space of volume defining a region around any one particular atom of interest (e.g. an atom involved in binding to an antibiotic), the volume being less than the total volume of the tetragonal space of the complete crystal. For example, the coordinates of atoms in a volume of from about 500 to about 15,000 $Å^3$ may be selected and used for the present invention. Such a space may be a sphere having a diameter of from about 10 Å to about 30 Å, centred around a point of interest; and

(c) a collection of at least 10, e.g. at least 25 such as at least 50, more preferably at least 100, even more preferably at least 500 atoms and most preferably at least 1000 atoms defined by the coordinates of Table N, wherein at least 2 of said atoms, and preferably at least 50% of said atoms of the collection are located within 50 Å of each other.

A "site" or "binding site" of the 30S is any part of this structure involved in binding to tRNA, mRNA or paromomycin, or regions whose conformation is altered by the binding of these molecules. Particular regions of the 30S include those identified herein as tRNA, mRNA or antibiotic binding regions based on the data provided in Table N. Depending on the particular molecule in the cavity, sites may exhibit attractive or repulsive binding interactions, brought about by charge, steric considerations and the like.

By "fitting", is meant determining by automatic, or semi-automatic means, interactions between one or more atoms of an potential inhibitor molecule and one or more atoms or binding sites of the 30S, and calculating the extent to which such interactions are stable. Various computer-based methods for fitting are described further herein.

By "root mean square deviation" we mean the square root of the arithmetic mean of the squares of the deviations from the mean.

"Computer readable media" refers to any media which can be read and accessed directly by a computer. Such media include, but are not limited to: magnetic storage media such as floppy discs, hard disc storage medium and magnetic tape; optical storage media such as optical discs or CD-ROM; electrical storage media such as RAM and ROM; and hybrids of these categories such as magnetic/optical storage media.

A "computer system" refers to the hardware means, software means and data storage means used to analyse the atomic coordinate data of the present invention. The minimum hardware means of the computer-based systems of the present invention comprises a central processing unit (CPU), input

means, output means and data storage means. Desirably a monitor is provided to visualise structure data. The data storage means may be RAM or means for accessing computer readable media of the invention. Examples of such systems are microcomputer workstations available from Silicon Graphics Incorporated and Sun Microsystems running Unix based, Windows NT or IBM OS/2 operating systems.

A "cognate" mRNA is an mRNA molecule which includes a triplet of nucleotides which are capable of base-pairing with the anti-codon loop of tRNA. Likewise, the term may be applied to tRNA which has an anticodon loop defining a sequence which base pairs to a triplet found in an mRNA.

Table N.

The coordinates of Table N provides a measure of atomic location in Angstroms, to a third decimal place. In order to use the information in these Tables for the purposes described herein as being aspects of the present invention, these coordinates may be varied by up to $\pm$ 1.0, such as by up to $\pm$ 0.7, preferably no more than up to $\pm$0.5 Angstroms, without departing from the scope of the invention.

Furthermore, varying the relative atomic positions of the atoms of the structure so that the root mean square deviation of the 16S RNA or S2-S20 protein backbone atoms is less than 1.5Å (preferably less than 1.0Å and more preferably less than 0.5Å) when superimposed on the coordinates provided in a Table N for the 30S structures, will generally result in a structure which is substantially the same as the structure of that Table N in terms of both its structural characteristics and potency for structure-based drug design of 30S inhibitors.

Thus for the purposes described herein as being aspects of the present invention, it is within the scope of the invention if:

the coordinates of a Table are transposed to a different origin and/or axes; the relative atomic positions of the atoms of the structure are varied so that the root mean square deviation of conserved residue backbone atoms is less than 1.5Å (preferably less than 1.0Å and more preferably less than 0.5Å) when superimposed on the coordinates provided in Tables 1 for the conserved residue backbone atoms; and/or the number and/or positions of water molecules is varied. Reference herein to the use of the coordinates of a Table N thus includes the use of coordinates in which one or more individual values of the Table is varied in this way.

Table N includes coordinates of metal ions which are selected from zinc and magnesium. Some or all of these ions may optionally be discarded from the Table when using the data. The Tables also list the coordinates of a 26 amino acid peptide, Thx. The coordinates of Thx may likewise optionally be discarded, i.e. so that the coordinates of the 16S mRNA and the proteins S2 to S20 alone are modelled and used in applications of the invention.

There are a few N- or C-terminal sequences of the S2 to S20 proteins which were not resolved in the structure of Table N, together with a some of the 5' and 3' residues of the 16S RNA. These are not essential for the purposes of the present invention.

This invention provides those of skill in the art a means to provide 30S crystals of *T.thermophilus* bound to tRNA and mRNA, and/or the antibiotic paromomycin. The conservation of ribosome structure, particularly regions of structure essential for function, between prokaryotes, for example prokaryotes which are human pathogens, such as Staphylococcus spp, and the like, allows the structure herein to be useful in the provision of anti-bacterial agents in general.

The 30S crystal structure.

The high resolution structure provided herein provides a crystal with unit cell dimensions which are provided in the accompanying table to 3 decimal places, as set out above. However, those of skill in the art wishing to reproduce the crystallization described herein and obtain such crystals will appreciate that a degree of experimental error will mean that crystals of the invention will be obtained with a unit cell dimension within, but not exactly corresponding to, this size. Thus crystals of the invention may generally be defined as having unit cell dimensions a, b, and c as defined above in which a and b vary by no more than $\pm$ x Å, and c varies by no more than $\pm$ 2x, where x is no more than 1.0 Å such as no more than 0.7 Å such as no more than 0.5 Å, such as no more than 0.2 Å. These unit cell sizes are believed to define novel and more highly resolved unit cell sizes than has previously been possible in the art.

Production of crystals.

To obtain crystals according to the present invention, we have found that selective removal of the S1 subunit protein is advantageous. This may be achieved by the use of hydrophobic interaction chromatography, poly(U) sepharose or by gel electrophoresis. Examples of this are illustrated in the accompanying examples:

Example 1

A suitable method for the selective removal of the S1 subunit protein is by the use of a hydrophobic interaction chromatography column (poros-ET). 30S ribosomal subunits lacking the S1 subunit may suitably be separated from those containing the S1 subunit by running a column using a reverse ammonium sulfate gradient from 1.5M to 0.5M, with 20mM Hepes, pH 7.5, and 10mM acetate. The 30S subunits lacking S1 are

eluted first, giving the first major peak. During elution of the 30S peak the ammonium sulfate concentration is maintained at a constant level. Once the 30S peak has eluted the ammonium sulfate concentration is then further reduced to elute the 30S + S1 fraction.

Example 2

An alternative method for the selective removal of the S1 subunit protein is by preparative gel electrophoresis. Gel electrophoresis may suitably be carried out by first preparing and mixing a 3% acrylamide, 0.5% agarose cylindrical gel, and pouring this gel into a BioRad Prep Cell. 30S ribosomal subunits are then loaded onto the gel and continuously eluted as they emerge form the other end of the gel. The 30S fraction lacking the S1 subunit comes off first, giving the first major peak. The 30S + S1 fraction gives the trailing peak (or shoulder) and can be discarded.

Once the S1 is removed, the crystals may be formed, using suitable conditions. These include the use of 13-17% v/v methyl-2,4-pentanediol in the presence of 200-300 (e.g. about 250) mM KCl, 50-100 (e.g. about 75) mM ammonium chloride, 15-30 (e.g. about 15 or about 25) mM $MgCl_2$ at a pH of 6.0 - 7.0 (e.g. about pH 6.3 - 6.7 such as pH 6.5) in 50 - 150 (e.g. about 100) mM sodium or potassium cacodylate or MES (2-(N-morpholino)ethane sulphonic acid).

In a particular aspect, the conditions may comprise the use of 250 mM KCl, 75 mM NH_4Cl, 25 mM $MgCl_2$, 6 mM 2-mercaptoethanol in 0.1 M potassium cacodylate or 0.1 M MES (2-N-morpholino-ethanesulfonic acid) at pH 6.5 with 13-17% MPD as the precipitant.

The crystals may be grown by any suitable method known as such to those of skill in the art. Suitably, the crystals may be

grown over a period of 4-8 weeks at about 4°C. Once crystals are obtained, the tRNA and mRNA, if required, may be soaked into the crystals. A concentration of from 100 to 300 μM is suitable for this purpose. An antibiotic, such as paromomycin, may be soaked in, in addition or in the alternative. The antibiotic may be used in any convenient soluble form at a concentration range of from 10 to 500 μM, preferably from 50 to 100 μM, such as about 80 μM. The structure of the crystals so obtained may be resolved to a resolution of at least 3Å. Crystals obtainable by such a method are also a further aspect of the invention.

Use of structure of Table N.

The determination of the three-dimensional structure of 30S provides a basis for the design of new and specific inhibitors for 30S. For example, knowing the three-dimensional structure of 30S, computer modelling programs may be used to design different molecules expected to interact with possible or confirmed sites, such as binding sites or other structural or functional features of 30S. Specific uses of Tables 1 to 3 include:

Table 1.

The data presented in Table 1 may be used to model the binding of tRNA and mRNA to the 30S ribosome. In addition, the data provide an indication of the various steric changes which the 30S ribosome undergoes when tRNA and mRNA bind to it. The shape of the 30S ribosome when bound may be used to model potential inhibitors of bacterial protein synthesis, e.g. by fitting potential inhibitors into the structure of 30S provided by table 1 or a sub-domain thereof involved in binding to mRNA and/or tRNA. Such inhibitors will bind to the 30S ribosome in competition with tRNA or mRNA, and thus inhibit the progress of translation. Such inhibition may either slow down the rate of translation or provide for

premature termination of the translation process.

Table 2.

The structure of the 30S which additionally to that of Table 1 includes the binding of paromomycin may additionally be used to examine potential inhibitor compounds which act at a similar site to paromomycin and exert a similar effect on the structure of the 30S.

Table 3.

This structure may also be used to examine potential inhibitor compounds which act at a similar site to paromomycin.

Inhibitor Fitting.

The high resolution models of the 30S provided by Table N can be used to examine the binding of tRNA, mRNA and or to the ribosome. By using this information, the skilled person in the art can design potential in which may be useful as antibiotics.

More specifically, a potential inhibitor capable of modulating 30S activity can be examined through the use of computer modelling using a docking program such as GRAM, DOCK, or AUTODOCK (see Walters et al., *Drug Discovery Today*, Vol.3, No.4, (1998), 160-178, and Dunbrack et al., *Folding and Design*, 2, (1997), 27-42) to identify potential inhibitors of 30S. This procedure can include computer fitting of potential inhibitors to 30S to ascertain how well the shape and the chemical structure of the potential inhibitor will bind to the structure.

Also computer-assisted, manual examination of the tRNA, mRNA and paromomycin binding sites of the 30S may be performed. The use of programs such as GRID (Goodford, *J. Med. Chem.*, 28,

(1985), 849-857) - a program that determines probable interaction sites between molecules with various functional groups and the enzyme surface - may also be used to analyse the active site to predict partial structures of potential inhibitors for the site.

Computer programs can be employed to estimate the attraction, repulsion, and steric hindrance of the two binding partners (e.g. the 30S and a potential inhibitor). Generally the tighter the fit, the fewer the steric hindrances, and the greater the attractive forces, the more potent the potential inhibitor since these properties are consistent with a tighter binding constant. Furthermore, the more specificity in the design of a potential inhibitor, the more likely it is that it will not interact with other proteins as well. This will tend to minimise potential side-effects due to unwanted interactions with other proteins.

In one embodiment a plurality of candidate inhibitor compounds are screened or interrogated for interaction with the binding sites. In one example, identification of a potential inhibitor involves providing the structures of the candidate agent compounds, each of which is then fitted in step (c) to computationally screen a database of compounds (such as the Cambridge Structural Database) for interaction with the binding sites.

In one aspect, the above described methods may be used to perform a computer-based method of rational drug design which comprises:

providing the structure of the 30S ribosome defined by the coordinates of Table N;

providing the structure of a candidate inhibitor molecule; and

fitting the candidate to the structure of the 30S.

It will be understood that the phrase "the structure of the 30S ribosome defined by the coordinates of Table N" as used above and elsewhere herein is reference to the coordinates defined by atoms 1-51527 of Table 1, 1-51536 of Table 2, or 1-51514 of Table 3, optionally also including the Thx and/or any or all of the metal ions defined by Table N.

In an alternative aspect, the method of the invention may utilise the coordinates of atoms of interest of the 30S which are in the vicinity of the tRNA, mRNA and/or paromomycin binding region in order to model the pocket in which these molecules bind. These coordinates may be used to define a space which is then screened *"in silico"* against a candidate inhibitor molecule. Thus the invention provides a computer-based method of rational drug design which comprises:

providing the coordinates of at least one atom of Table N of the 30S ribosome;

providing the structure of a potential inhibitor molecule; and

fitting the structure of potential inhibitor to the coordinates of the 30S ribosome.

In this embodiment, the at least one atom of the 30S ribosome provided will preferably be an atom of a base of the 16S RNA selected from C518, G530, C1054, A1492 and A1193, or an atom of the S12 amino acids Ser59 or Pro48.

In practice, it will be desirable to model a sufficient number of atoms of the 30S ribosome as defined by the coordinates of Table N which represent a binding region for tRNA and/or mRNA. Such binding regions and other features are described in the accompanying example. Thus, in this embodiment of the invention, there will preferably be provided the coordinates of at least 5, preferably at least 10, more preferably at

least 50 and even more preferably at least 100 atoms such as at least 500 and more preferably at least 1000 atoms of the 30S ribosome. Of these atoms provided, at least one will preferably be from the 16S RNA or S12 polypeptide as defined above.

Having designed or selected potential inhibitors, these can then be screened for activity. Consequently, the method preferably further comprises the further steps of:

obtaining or synthesising the potential inhibitor; and

contacting the potential inhibitor with 30S to determine the ability of the potential inhibitor to interact with 30S.

More preferably, in the contacting step the potential inhibitor is contacted with 30S under conditions to determine its function, for example in a cell free translation system.

Instead of, or in addition to, performing such an assay, the method may comprise the further steps of:

obtaining or synthesising said potential inhibitor;

forming a complex of 30S and said potential inhibitor; and

analysing said complex by X-ray crystallography to determine the ability of said potential inhibitor to interact with 30S. Detailed structural information can then be obtained about the binding of the potential inhibitor to 30S, and in the light of this information adjustments can be made to the structure or functionality of the potential inhibitor, e.g. to improve binding to the active site. The above steps may be repeated and re-repeated as necessary.

Another aspect of the invention includes a compound which is identified as an inhibitor of 30S by the method of the above aspects of the invention.

Following identification of an inhibitor compound, it may be manufactured and/or used in the preparation, i.e. manufacture or formulation, of a composition such as a medicament, pharmaceutical composition or drug. These may be administered to individuals.

Thus, the present invention extends in various aspects not only to an inhibitor as provided by the invention, but also a pharmaceutical composition, medicament, drug or other composition comprising such an inhibitor e.g. for treatment (which may include preventative treatment) of disease such as microbial infection; a method comprising administration of such a composition to a patient, e.g. for treatment of disease such as microbial infection; use of such an inhibitor in the manufacture of a composition for administration, e.g. for treatment of disease such as microbial infection; and a method of making a pharmaceutical composition comprising admixing such an inhibitor with a pharmaceutically acceptable excipient, vehicle or carrier, and optionally other ingredients.

In another aspect, the invention provides a method of analysing a 30S-ligand complex wherein the ligand is an inhibitor which has been obtained by the methods of the invention described above, comprising the steps of (i) cocrystallising the 30S with the ligand or soaking the ligand into crystals of the 30S; (ii) collecting X-ray crystallographic diffraction data from the crystals of the 30S-ligand complex and (iii) using the three-dimensional structure of 30S of Table N, or at least one sub-domain thereof, to generate a difference Fourier electron density map of the 30S-ligand; and (iv) modelling the ligand in the difference Fourier electron density.

Therefore, 30S-ligand complexes can be crystallised and

analysed using X-ray diffraction methods, e.g. according to the approach described by Greer et al., *J. of Medicinal Chemistry*, Vol. 37, (1994), 1035-1054, and difference Fourier electron density maps can be calculated based on X-ray diffraction patterns of soaked or co-crystallised 30S and the solved structure of uncomplexed 30S. These maps can then be used to determine the structure of the ligand bound to the 30S and/or changes the conformation of 30S.

Electron density maps can be calculated using programs such as those from the CCP4 computing package (Collaborative Computational Project 4. The CCP4 Suite: Programs for Protein Crystallography, *Acta Crystallographica*, D50, (1994), 760-763.). For map visualisation and model building programs such as "O" (Jones et al., *Acta Crystallograhy*, A47, (1991), 110-119) can be used.

By providing such computer readable media, the atomic coordinate data can be routinely accessed to model 30S or a sub-domain thereof. For example, RASMOL is a publicly available computer software package which allows access and analysis of atomic coordinate data for structure determination and/or rational drug design.

On the other hand, structure factor data, which are derivable from atomic coordinate data (see e.g. Blundell et al., in *Protein Crystallography*, Academic Press, New York, London and San Francisco, (1976)), are particularly useful for calculating e.g. difference Fourier electron density maps.

In another aspect, the present invention provides systems, particularly a computer systems, intended to generate structures and/or perform rational drug design for 30S ligand complexes, the systems containing either (a) atomic coordinate

data according to Table N, said data defining the three-dimensional structure of 30S or at least one sub-domain thereof, or (b) structure factor data for 30S, said structure factor data being derivable from the atomic coordinate data of Table N.

The invention is illustrated below by the following examples, their accompanying Figures and Tables. In Tables N (1 to 3) there is shown in each row Atom number, element type, residue (amino acid, nucleotide, etc), number in molecule (for proteins N to C terminal direction, for nucleic acid 5' to 3' direction), X, Y and Z co-ordinates, occupancy, B factor ($Å^2$) and an identifier for the member of the 30S (e.g. for the subunits in the format "ASn" where A is an arbitrary letter, different for each member, S is the subunit and n is the subunit number; and for the 16S as "A16S").

Crystal structures of the 30S ribosomal subunit have been solved in complex with mRNA and cognate tRNA in the A site, both in the presence and absence of the antibiotic paromomycin. Cognate tRNA binding induces global domain movements of the 30S subunit and changes in the conformation of the universally conserved and essential bases A1492, A1493 and G530 of 16S RNA. These bases interact intimately with the minor groove of the first two base pairs between the codon and anticodon, thus sensing Watson-Crick base pairing geometry and discriminating against near-cognate tRNA. The third, or "wobble" position of the codon is free to accommodate certain non-canonical base pairs. By partially inducing these structural changes, paromomycin facilitates binding of near-cognate tRNAs.

Structure Determination

Recently, we showed that the A site in our crystal form is accessible by diffusion to macromolecules as large as

initiation factor IF1 (25). Based on this experience, a 17 nucleotide fragment corresponding to the ASL of $tRNA^{phe}$ with a GAA anticodon, along with a U_6 hexanucleotide that would place a codon for phenylalanine in the A-site were soaked into crystals of the 30S subunit (26). Diffraction data to 3.1 - 3.3 Å resolution were collected from such crystals both in the absence and presence of paromomycin, as well as from crystals of the 30S subunit soaked in paromomycin alone (see table in Examples below). Initial refinement was done using the native 30S subunit structure (PDB entry 1FJF) (17) as a starting model, with the occupancies of the atoms for parts of the structure in the vicinity of A-site tRNA initially set to zero to avoid possible bias (26). Clear density for the A-site codon and tRNA ASL, and elements of the 30S subunit that had changed conformation such as A1492, A1493 and G530 were visible in difference Fourier electron density maps for the complexes both in the absence and presence of paromomycin. These elements were subsequently built into the maps for each of the individual structures, and a final refinement was done with all atoms visible in the electron density, including metal ions. Statistics for the refinement are shown in the table below. A σ_A-weighted $2mF_o - DF_c$ map after refinement was also calculated.

Overview of mRNA and tRNA in the A site

The structure reveals details of mRNA and tRNA binding to the 30S subunit. In our native 30S subunit structure, the 3' end of 16S RNA is folded back into the message binding cleft of the 30S subunit, and thus mimics mRNA in the P and E sites (21). The P site is also occupied by a stem-loop that mimics tRNA and comes from helix 6 of a neighboring molecule in the crystal. These features are also seen in all the complexes described below. Additionally, in the structures with the ASL and U_6 hexanucleotide, we can clearly see the three nucleotides from the A-site codon, and slightly less well-defined density

for a fourth nucleotide 3′ of the A site. The electron density for the mRNA between the P and A sites appears continuous despite the fact that there is a covalent break in the chain between the P- and A-site codons. As reported earlier at lower resolution (24), there is a distinct kink in the path of the mRNA between the A- and P-site codons. In addition, we can now see in detail how the ASL of cognate tRNA interacts with the A-site codon and the 30S subunit. The structure of the ASL, which does not contain any modified nucleosides, is very similar to that of isolated yeast phenylalanine tRNA (27, 28) or of *Thermus* phenylalanine tRNA complexed with aminoacyl synthetase (29). The contacts of the ASL to the 530 loop, helix 34 and helix 44 of the ribosome arise solely from the anticodon loop.

Recognition of cognate tRNA in the ribosome by an induced fit

The binding of mRNA and cognate tRNA in the A site induces A1492 and A1493 to flip out of the internal loop of helix 44. This binding also causes the universally conserved base G530, which has been foot-printed by A-site tRNA (13), to switch from the *syn* conformation present in the native structure to an *anti* conformation. In their new conformations, A1493 and A1492 interact with the first and second base pairs of the codon-anticodon helix, while G530 interacts with both the second position of the anticodon and the third position of the codon. The result of these induced changes is that the first two base-pairs of the codon-anticodon helix are closely monitored by the ribosome in a way that would be able to discriminate between Watson-Crick base pairing and mismatches, while the environment of the third, or "wobble," position appears to be suited for accommodating other base-pairing geometries (30, 31).

A1493 packs tightly in the minor groove of the first base-pair

of the codon-anticodon helix, so that there are hydrogen bonds between the 2' OH of the A1493 and the 2' OH of the first nucleotide of the codon, as well as between N1 of A1493 and the 2' OH of position 36 of the anticodon (Figure 1A). Additionally, a hydrogen bond is evident from the 2' OH of A1493 to the O2 of the uracil in the codon. Although this bond involves the base, it is not sequence specific because the O2 of pyrimidines and the N3 of purines are hydrogen bond acceptors that occupy equivalent positions in the minor groove of Watson-Crick base pairs (32). In the case of a GC or CG base pair at the first codon position, it would be possible to form an additional bond from the N3 of the A1493 to the N2 of the guanine.

A1492 and G530 together bind in and span the minor groove of the second base-pair of the codon-anticodon helix (Figure 1B), and their orientation relative to one another is stabilized in part by a hydrogen bond between their N1 positions. They make equivalent interactions with each strand of the codon-anticodon helix in that the 2' OH of the codon hydrogen bonds to the N3 and the 2' OH of A1492, while the 2' OH of tRNA hydrogen bonds to the N3 and 2' OH of G530. In addition, the N6 of A1492 is involved in hydrogen bonding to the 2' OH of the universally conserved C518, as well as to the highly conserved Ser50 (*E. coli* Ser46) of the nearby protein S12. The loop of S12 containing this serine (Thr44 to Ala51; *E. coli* residues 40-47) is the site of mutations that affect the fidelity of translation (reviewed in 33). As with the first base pair, the close fit of van der Waals surfaces and various interactions in the minor groove would be sensitive to whether the second base-pair had Watson-Crick geometry or not.

Unlike the first two base-pairs, the geometry of the third base-pair between the codon and anticodon, which in our structure is a GU base pair, is not as closely monitored by

the ribosome (Figure 1C). The 2' OH of the codon makes a hydrogen bond with the O6 of G530 as well as an indirect metal-mediated interaction with the O2 of C518 and the main chain carbonyl of Pro48 (*E. coli* Pro44) of protein S12. In addition, the pyrimidine O2 of the anticodon and the O6 of G530 are in close contact. The ribose of the anticodon packs against C1054 from helix 34 in the head of the ribosome. These interactions leave the minor groove of this base pair, especially on the anticodon side, relatively open as compared to the first two positions. Since non-canonical base pairs alter the shape and possible interactions in the minor groove, the structure shows why some of these are allowed in the wobble position. Also, the mRNA nucleotide in this position makes more interactions with the ribosome than does the tRNA, confirming predictions that its conformation should be the more restricted of the two (31).

The geometry of the first two base pairs of the codon-anticodon helix is very similar in the presence and absence of paromomycin, with a slightly less planar base pair in the first position in the presence of paromomycin. In the absence of paromomycin, the geometry for the third position deviates from that expected for a wobble pair (Figure 1C), but the expected wobble geometry is seen in the higher resolution structure in the presence of paromomycin (Figure 1D). Since we see occasional departures from ideality in other parts of the 30S subunit structure, it is clear that higher resolution will be needed to make definitive statements about deviations from standard geometry.

The structure is consistent with most chemical protection (13) and genetic data (15) on A-site tRNA binding. The finding that A1492 and A1493 are required for viability (18) is rationalized by the observation that the smaller pyrimidines could not reach far enough to make interactions with tRNA or

G530, and that guanine would not only have a steric clash at its N2 position, but would also not be able to hydrogen-bond through its N1 in the same way. The requirement for guanine at position 530 (34) can be similarly rationalized, since its N1 is required to hydrogen bond with the N1 of A1492, and its O6 is required to hydrogen bond with the 2' OH of the uridine at the third position of the codon. While A1492 and A1493 flip out of helix 44 and monitor the minor groove of the codon-anticodon helix roughly as we had proposed, the details of the interactions are different from those in the two motifs found in the structure of 16S RNA that we had suggested as possible ways for adenines to recognize the codon-anticodon helix (21). Also, the N1 of these adenines interact with the 2' OH of tRNA or with the N1 of G530, rather than with the 2' OH groups of mRNA as proposed previously (18). Finally the structure does not support a model in which the N6 of these adenines forms a hydrogen bond with the O2 of pyrimidines or N3 of purines on mRNA (23).

Both the structural interactions and the general strategy in decoding have similarities with other systems. The interactions that A1493 and A1492 make with the minor groove of the first two base pairs of the codon-anticodon helix are identical to tertiary interactions that occur in both the group I intron (35) and the structure of 23S RNA (36), and classified as consecutive "Type I" and "Type II" A-minor motif interactions (37). These interactions always involve conserved adenines, and a major part of the stabilization energy arises from the complementarity of the adenines with the surface of the minor groove (38). Similar tertiary interactions involving tight packing of conserved adenines in minor grooves of adjacent helices have also been reported previously in the 16S RNA structure (17, 21).

The strategy adopted by the ribosome to recognize correct base

pairing has similarities and differences with other template-directed enzymes that have high fidelity such as DNA and RNA polymerases. These enzymes also make close interactions with the minor groove of the base pair to be formed. In DNA polymerases, conserved arginines or glutamines form hydrogen bonds to the O2 of pyrimidines or N3 of purines (39, 40). In our structures, A1493 does make a similar hydrogen bond with the O2 of uracil in monitoring the first codon base. However, the ribosome mainly forms bonds with the ribose 2' OH groups on both strands of the codon-anticodon helix, which are not available to DNA polymerases. Interestingly, T7 RNA polymerase also forms hydrogen bonds to 2' OH moieties of the incoming ribonucleotide and the RNA transcript (41). It is clear that the ribosome, like polymerases, senses the shape and available interactions at the minor groove to ensure fidelity.

Effect of paromomycin

The effects of tRNA and paromomycin on the 30S subunit are shown schematically in Figure 2. In the native structure (17), A1492 and A1493 are stacked in the interior of helix 44 (Figure 2A), and G530 is stacked in the 530 loop in the *syn* conformation. The binding of paromomycin flips out A1492 and A1493 (Figure 2B). The structure of the decoding site in the presence of paromomycin alone is essentially identical to that determined previously in the presence of paromomycin, streptomycin and spectinomycin (21), showing that the changes induced in this region are solely due to the binding of paromomycin. However, in the absence of tRNA, paromomycin does not have an effect on G530, which remains in the *syn* conformation. The binding of A-site tRNA flips out G530 into the *anti* conformation (Figure 2C); it also flips out A1492 and A1493, but they are not in exactly the same conformation as with paromomycin alone (compare Figure 2B and C). In the presence of cognate A-site tRNA, the additional presence of

paromomycin (Figure 2D) does not result in further changes in the conformation of these bases (compare Figure 2C and D).

The structures provide firm evidence that the changes induced in the 30S subunit by cognate tRNA are energetically favorable because various compensating interactions can be made by the ribosome with the codon-anticodon helix, but only when the first two base-pairs are canonical Watson-Crick base pairs. In the case of near-cognate tRNA, fewer of these interactions would be possible, so the induced changes would normally be less favorable. By paying part of the energetic cost of these induced changes, especially in displacing A1492 and A1493 from their internal loop in helix 44, paromomycin facilitates the binding of near-cognate tRNAs, along with the full changes induced as a result. This model is consistent with the finding that paromomycin accelerates precisely those steps (GTP hydrolysis and accommodation) for near-cognate tRNA that are normally slower as compared to cognate tRNA (8) and agrees with earlier proposals that paromomycin works by inducing structural changes in the decoding site (21, 22) rather than by making direct interactions with mRNA or tRNA (23). The structure also explains the classical result that single stranded DNA is not normally a good template for protein synthesis, but becomes so in the presence of the antibiotics neomycin and kanamycin that are closely related to paromomycin (42). Since the 2' OH groups are not present on DNA, the induced structural changes on cognate tRNA binding are not normally favorable because fewer interactions are possible. However, just as with normal translation, aminoglycosides can pay for part of the energetic cost of the induced changes and stabilize tRNA binding.

Other conformational changes during decoding

During accommodation, the A-site tRNA has to rotate

significantly from its initial orientation as part of the ternary complex with EF-Tu to its final position in the A site where its acceptor end is accessible to peptidyl transferase (43, 44). From an examination of the A-site tRNA in 70S ribosome structures (24, 45, 46), it appears that the position of the ASL in our structure is close to the tRNA orientation after accommodation. Since most of the selectivity of cognate over near-cognate tRNA appears to come from the accommodation step (7), the structure we see is likely to be relevant for understanding the specificity of the ribosome for cognate tRNA. A high resolution structure of the EF-Tu ternary complex bound to the ribosome will be required to understand details of the initial recognition step. However, it is likely that many of the changes induced by cognate tRNA are initiated during the binding of the ternary complex, and that the resulting interactions of the ribosome with the codon-anticodon helix persist during the subsequent movement of the tRNA.

A key question that remains to be answered is how the changes around the decoding site induced by cognate tRNA are transmitted to EF-Tu to trigger GTP hydrolysis. The binding of cognate tRNA results in a movement of the head and shoulder of the 30S subunit towards each other in a way that closes around the A-site tRNA. These changes are even greater when paromomycin is bound in addition to cognate tRNA, with as much as a 4 Å relative movement between the head and shoulder. As with the binding of IF1 (25), it is likely that we do not see the full extent of conformational changes because of the constraints of the crystal lattice. It is possible that these changes reflect the types of changes in the 30S subunit that occur on the binding of the EF-Tu ternary complex, which may be transmitted to the 50S subunit and be part of the trigger for GTP hydrolysis by EF-Tu. Another possibility, suggested on the basis of experiments in which the acceptor arm and the

anticodon stem-loop of cognate tRNA were present as two separate fragments, is that the signal to EF-Tu is transmitted through tRNA itself (47).

Conclusions

This work shows that the ribosome recognizes the geometry of codon-anticodon base pairing in a way that would discriminate against near-cognate tRNAs. The minor groove of the first and second base-pairs between the codon and anticodon are closely monitored by a set of interactions that are induced by the binding of cognate tRNA. These interactions would be disrupted by mismatches, so that the induced structural changes would no longer be energetically favorable. The third or "wobble" position has less stringent constraints, and therefore can allow a broader range of base-pairing geometries, consistent with the requirements of the genetic code. The binding of paromomycin partially induces the changes that normally are induced by cognate tRNA. By paying part of the energetic cost of these induced changes, paromomycin facilitates the increased incorporation of amino acids from near-cognate tRNAs.

Figure 1. Interactions of the ribosome with the codon-anticodon base pairs. The tightness of the interactions is shown by the semitransparent van der Waals surface. (A) In the first position, A1493 binds in the minor groove of the A36-U1 base pair. (B) In the second position, G530 and A1492 act in concert to monitor the A35-U2 base pair. (C) The third (wobble) position, showing the G34-U3 base pair. C1054 stacks against G36 of the ASL. U3 interacts with G530, and indirectly through a Mg ion with C518 and residue Pro48 (*E. coli* Pro44) from protein S12. The base pair seems closer to Watson-Crick geometry. (D) The third position in the presence of paromomycin, with the expected G•U wobble pair. The interactions with the ribosome are similar to (C).

Figure 2. Discrete states of the A site of the 30S subunit, as deduced from four different crystal structures. In all panels, the tRNA ASL, A-site codon, P-site mRNA, protein S12 , and important bases involved in conformational changes are shown. A few elements of the 16S RNA such as helix 44 (lower right), 530 loop (mid and lower left), and helix 34 (upper left) are also shown. (A) The native 30S subunit (17). A1492/3 (right) are stacked in the interior of H44, and G530 is in the *syn* conformation. C1054 is shown in the upper left corner. (B) In the presence of paromomycin, the bases of A1492 and A1493 have been displaced into the A site by the binding of the antibiotic inside helix 44 (lower right). (C) When the codon and cognate tRNA-ASL bind in the A site, A1492/3 flip out to monitor the codon-anticodon interaction and G530 has switched to the *anti* conformation to interact with A1492, the anticodon in the second position and the codon in the third. Two Mg ions are visible near the region vacated by A1492/3 in the interior of helix 44 and one is located close to the ribose of the codon in the wobble position (see Figure 1C/D). (D) When paromomycin is present in addition to tRNA-ASL and codon, the structure is very similar to (C).

Summary of crystallographic data

(a) Data collection

Data set	U6 / ASL	U6 / ASL / Paromomycin	Paromomycin
Beamline	SBC 19ID	SBC 19ID	SBC 19ID

26. Crystals of the 30S subunit from *Thermus thermophilus* were grown as previously described (17). A $tRNA^{Phe}$ anticodon stem-loop (ASL) corresponding to the sequence GGGGAUUGAAAAUCCCC, and the U_6 hexanucleotide were synthesized chemically. The ASL was purified by gel-electrophoresis and the U_6 by reverse phase chromatography. Crystals were transferred to a stabilizing buffer containing 26% 2-methyl-2,4-pentanediol (MPD) as described (17). Soaks of equimolar ASL and U_6 were done at a concentration of 100 or 300 μM in the same stabilizing buffer, while paromomycin, if present, was at a concentration of 80 μM. Initial screening of crystals was done at beamlines 14.1 and 14.2 at the Synchrotron Radiation Source at Daresbury Laboratory, where a 3.8 Å resolution data set on one of the soaks was also collected. All data to high resolution were collected at beamline SBC-19ID at the Advanced Photon Source at Argonne National Laboratory, integrated and scaled using HKL-2000 (48). The atomic structure of the 30S subunit (17), omitting various parts near the A site, was used as a starting point for refinement against the three data sets using CNS (49). Initially, rigid body refinement was done using the domains of 16S RNA and the individual proteins as separate rigid objects. This was followed by positional refinement, simulated annealing using torsion angle dynamics, followed by two rounds of grouped B-factor refinement and refinement of the occupancies of metal ions. The ASL (15 and 11 residues in the presence and absence of paromomycin,

respectively), mRNA, and any changes in the 30S subunit, were built into the density in difference Fourier maps using the program O (50) before a final round of refinement.
